

Problem Set 4

Your Name - Net ID - Section Number

Due Dec 13, 2023

This homework must be turned in on Brightspace by Dec. 13 2023. It must be your own work, and your own work only – you must not copy anyone’s work, or allow anyone to copy yours. This extends to writing code. You may consult with others, but when you write up, you must do so alone.

Your homework submission must be written and submitted using Rmarkdown. No handwritten solutions will be accepted. **No zip files will be accepted. Make sure we can read each line of code in the pdf document.** You should submit the following:

1. A compiled PDF file named yourNetID_solutions.pdf containing your solutions to the problems.
2. A .Rmd file containing the code and text used to produce your compiled pdf named your-NetID_solutions.Rmd.

Note that math can be typeset in Rmarkdown in the same way as Latex. Please make sure your answers are clearly structured in the Rmarkdown file:

1. Label each question part
2. Do not include written answers as code comments.
3. The code used to obtain the answer for each question part should accompany the written answer. Comment your code!

Problem 1 (100 points)

Despite the heated political and media rhetoric, there are a few causal estimates of the effect of expanded health insurance on healthcare outcomes. One landmark study, the Oregon Health Insurance Experiment, covered new ground by utilizing a randomized control trial implemented by the state of Oregon. To allocate a limited number of eligible coverage slots for the state's Medicaid expansion, about 30,000 low-income, uninsured adults (out of about 90,000 wait-list applicants) were randomly selected by lottery to be allowed to apply for Medicaid coverage. Researchers collected observable measure of health (blood pressure, cholesterol, blood sugar levels, and depression), as well as hospital visitations and healthcare expenses for 6,387 selected adults and 5,842 not selected adults.

For this problem, we will use the OHIE.dta file.

- treatment - selected in the lottery to sign up for Medicaid (instrument)
- ohp_all_ever_admin - Ever enrolled in Medicaid after notification of lottery results (compliance)
- tab2bp_hyper - Outcome: Binary indicator for elevated blood pressure (1 indicates a high blood pressure)
- tab2phqtot_high - Outcome: Binary indicator for depression
- tab4_catastrophic_exp_inp - Outcome: Indicator for catastrophic medical expenditure (1 if their total out-of-pocket medical expenses are larger than 30% of their household income)
- tab5_needmet_med_inp - Outcome: Binary indicator of whether the participant feels that they received all needed medical care in past 12 months

```
# Load in the data
data <- haven::read_dta("OHIE.dta")
```

Hint: This was an experiment with imperfect compliance. Instead of creating a “participated” or “complied” variable, simply use “treatment” as the instrument and “ohp_all_ever_admin” (enrollment in Medicaid) as the main independent variable of interest.

Question A (25 points)

Estimate the intent-to-treat effects of being selected to sign up for Medicaid on each of the four outcomes (elevated blood pressure, depression, catastrophic medical expenditure, and whether respondents had their health care needs met). Provide 95% confidence intervals for each estimate and interpret your results. (Use `lm_robust`)

```
# Estimate the ITT on elevated blood pressure
```

```
# Estimate the ITT on depression
```

```
# Estimate the ITT on catastrophic expenditures
```

```
# Estimate the ITT on "needs met"
```

Question B (25 points)

Suppose that researchers actually wanted to estimate the effect of Medicaid enrollment (`ohp_all_ever_admin`) on each of the four outcomes. Suppose they first used a naive regression of each of the the outcomes on the indicator of Medicaid enrollment. Report a 95% confidence interval for each of your estimates and interpret your results. Why might these be biased estimates for the causal effect of Medicaid enrollment?

```
# Estimate the Naive OLS effect on elevated blood pressure
```

```
# Estimate the Naive OLS effect on depression
```

```
# Estimate the Naive OLS effect on catastrophic expenditures
```

```
# Naive OLS estimate on needs met
```

Question C (25 points)

Suppose we were to use assignment to treatment as an instrument for actually receiving Medicaid coverage.

Consider that not everyone who was selected to apply for Medicaid actually ended up applying and receiving coverage. Likewise, some applicants who were not selected to receive the treatment nevertheless were eventually covered. What were the compliance rates (the level of Medicaid enrollment) for subjects who were selected and subjects who were not selected? Use a “first stage” regression to estimate the effect of being selected on Medicaid enrollment to estimate the compliance rates. Is the instrument of assignment-to-treatment a strong instrument for actual Medicaid enrollment?

```
# First Stage OLS
```

```
# null model (compliance given an intercept only model)  
null_mod<-lm_robust(ohp_all_ever_admin ~ 1, data=data)
```

```
# F - Stat for Instrument Strength (use waldtest)
```

Question D (25 points)

Now estimate the effect of Medicaid enrollment on each of the four outcomes using an instrumental variables strategy. Report a 95% confidence interval for your estimates and interpret your results. Compare the estimates to those you obtained in Question B.

```
# Estimate the IV effect on elevated blood pressure (use iv_robust())
```

```
# Estimate the IV effect on depression
```

```
# Estimate the IV effect on catastrophic expenditures
```

```
# IV estimate on needs met
```
